

TV Ratings Prediction with Time Weighting Based Regression (TWR)

Master Thesis Defense

Student — Ting-Wei Ku (Martin)

Advisor — Prof. Shou-De Lin

Committee — Prof. Pu-Jen Cheng, Ph.D. Cheng-Te Li

National Taiwan University
Department of Computer Science & Information Engineering
Machine Discovery & Social Network Mining Lab

Feb 2, 2015

Agenda

- 1 Thesis Goal: Improve TV Ratings Prediction with MY NOVELTY
- 2 Related Work
- 3 Solution: Time Weighting Based Regression (TWR)
- 4 Experiments
- 5 Conclusion

Why TV ratings prediction?

It is an important, complex, and real-world problem with money.

- It's important because TV ratings decide **price of advertising time**.
- It's complex because. . .
 - TV ratings are **aggregate** measure of **many people's choices**.
 - TV is **competing** with many platforms/services (mobile/YouTube).

MY NOVELTY (Contribution) is TWR

- **Key idea:** Fit regression model with time-weighted instances.
- **Example:** Given x is a time series of ratings,
 - $(x_1, x_2, x_3, x_4=y_4), t=4, \text{weight}=4$
 - $(x_2, x_3, x_4, x_5=y_5), t=5, \text{weight}=5$
 - $(x_3, x_4, x_5, x_6=y_6), t=6, \text{weight}=6$
 - ... more weighted training instances
 - $(x_6, x_7, x_8, x_9=y_9), t=9, \text{testing instance}$
- **Assumption:** Intuitively, newer instances are more important.

We'll show how **effective** this **simple** solution is.

- 5 Conclusion

What TV ratings to predict?

- **Data:** 8 real-world weekly dramas (170 ratings) broadcast in TW
 - Originally from SET but now also available at Wikipedia
- Predict next ratings of each drama (1-step forecasting)
- Start making predictions from the 6th episode

Time Series Plot of Data

Figure 1: Time series plot of ratings

Box Plot of Data

Figure 2: Box plot of ratings

Basic Info of Data

Drama	# Episode	Start	Avg(ratings)	Std(ratings)
D1	16	2013/2/28	0.21	0.08
D2	25	2011/8/21	5.12	1.09
D3	22	2012/2/19	2.38	0.16
D4	21	2013/1/6	1.57	0.23
D5	21	2013/6/9	2.16	0.3
D6	19	2010/12/5	1.1	0.21
D7	23	2010/11/5	3.36	2.75
D8	23	2012/7/22	3.47	0.56

- 5 Conclusion

Code example

```
if (weight_type == 'equal') {  
  # this is known as bagging  
  case_weights <- rep(1 / num_cases, num_cases)  
} else if (weight_type == 'linear') {  
  case_weights <- seq(1, num_cases)  
} else if (weight_type == 'exp') {  
  case_weights <- exp(1:num_cases)  
} else if (weight_type == 'exp3') {  
  alpha <- 3  
  case_weights <- (exp(1)^alpha)^(1:num_cases)  
} else {  
  # decide weight type automatically via validation error  
}
```

Thank you! Any question?
